Comments

DRUG.CLASS	COMMENTS		
PI			
NRTI	M184V/I cause high-level in vitro resistance to 3TC and FTC and low/intermediate		
	resistance to ABC (3-fold reduced susceptibility). M184V/I are not contraindications to		
	continued treatment with 3TC or FTC because they increase susceptibility to AZT and		
	TDF and are associated with clinically significant reductions in HIV-1 replication.		
NNRTI	K103N is a non-polymorphic mutation that confers high-level reductions in NVP and EFV		
	susceptibility. It is the most commonly transmitted DRM.		
	V108I is a relatively non-polymorphic accessory mutation selected in vitro and/or in vivo		
	with each of the NNRTIs. It appears to contribute to reduced susceptibility to most		
	NNRTIs only in combination with other NNRTI-resistance mutations.
